**Abstract** — Our main goal is to use satellite technology and GIS (Geographic Information Systems) for an exploration of grape vegetation, with a focus on understanding the factors influencing optimal grape production. In this research, several possible factors impacting grape yield in Michigan has been explored from the data between 2001 and 2011. First, the relationship between NDVI and temperature, precipitation, dew point, and wind speed has been examined. Second, the relationship between NDVI and the yield of grapes in Michigan has been investigated. A regression model has been developed for this purpose. Increase in NDVI during the summer season has been detected. The relationship between NDVI and temperature, precipitation, dew point, and wind speed turned out to be statistically not significant. Similarly, the relationship between NDVI and the yield of grapes has no significance statistically.

## I. INTRODUCTION

**N**DVI stands for Normalized Difference Vegetation

Index. It's a numerical indicator used in remote sensing to assess and measure the amount of live vegetation in a given area. NDVI is calculated using the reflectance of near-infrared and red light from the Earth's surface.

$$NDVI = \frac{NIR - Red}{NIR + Red}$$

Where:

NIR is the reflectance of near-infrared light.

Red is the reflectance of red light.

It's widely used in agriculture, forestry, and ecology to monitor vegetation health, growth, and coverage over time. Previous research by Schultze et al. (2014) has explored the impacts of climatic variability on grape production. This study explores cool climate viticulture in response to the observed trend of increasing temperatures on Earth. This research investigates the trends of NDVI and concord grape yield in Michigan. Additionally, it examines the relationship between NDVI and various climatic factors including temperature, precipitation,

dew point, and wind speed. Furthermore, this study investigates the relationship between NDVI and the yield of concord grapes in Michigan.

## II. METHODS AND DATA SETS

To analyze the relationships, several methods were employed. Initially, a multiple regression model was utilized to examine the relationship between NDVI and variables including temperature, precipitation, dew point, and wind speed. Subsequently, a linear regression model was developed to explore the relationship between NDVI and grape yield. A diagram illustrating these relationships has been constructed and is presented below:

**Fig. 1.** First, the relationship between NDVI and temperature, precipitation, dew point, and wind speed, where NDVI is dependent variable and temperature, precipitation, dew point are dependent variable. Second, the relationship between NDVI and the yield of grapes, where NDVI is independent variable, and Grape Yield is dependent variable.

Initially, several studies have demonstrated a positive correlation between variables such as temperature and precipitation and NDVI (Raynolds et al., 2008). However, research investigating the connection between variables such as dew point and wind speed and NDVI has been limited. Therefore, this study considers the inclusion of these two variables.

Furthermore, Gozdowski et al. (2021) have reported a positive correlation between NDVI and crop yield in their research on the relationship between NDVI and yield of cereals in several European countries. Since research in the area of grapes associated with NDVI has been relatively scarce, this paper explores the analysis between these variables.

The concord grape yield data in Michigan from 2001 to 2011 were sourced from The National Grape Cooperative Network.

NDVI values were obtained using a multi-step process. Firstly, the shapefile of St. Julian vineyard in Michigan was extracted using QGIS software. Subsequently, these files were

imported into AppEEars, a web application provided by NASA, which allows users to select specific areas or import the shapefile, and access data from available satellites. For this study, data from the Terra and Aqua satellites were utilized. Additionally, the Moderate Resolution Imaging Spectroradiometer (MODIS) sensor, a satellite-based instrument for Earth observation, was employed. NDVI values were selected based on the grape bloom date and harvest completion date. To streamline data analysis, NDVI values were averaged to obtain yearly values based on the selected months.

Temperature and precipitation data were sourced from the National Weather Service by NOAA. Similar to NDVI values, data were selected based on specific months. For analysis, temperature values were averaged, while precipitation values were summed to obtain the total for the selected months. Dew point and wind speed data from the location were obtained from Weather Underground.

Table 1 presents all the values used to examine the relationships.

TABLE I  
CALCULATED VALUES FOR THE VARIABLES

| Year | Yield | NDVI       | Temperature(°F) | Precipitation(mm) | Dew Point(°F) | Wind Speed(mph) |
|------|-------|------------|-----------------|-------------------|---------------|-----------------|
| 2001 | 2.1   | 0.69646515 | 60.72857143     | 32.34             | 52.0171429    | 7.24            |
| 2002 | 2.8   | 0.73065    | 59.44285714     | 18.54             | 49.9028571    | 7.15285714      |
| 2003 | 5.3   | 0.71640186 | 58.82857143     | 26.83             | 49.6357143    | 7.06142857      |
| 2004 | 3.7   | 0.73101852 | 59.85714286     | 27.03             | 50.3871429    | 6.93            |
| 2005 | 7.1   | 0.71677    | 61.74285714     | 24.71             | 50.6642857    | 7.04571429      |
| 2006 | 1.6   | 0.72915833 | 60.02857143     | 28.41             | 49.2614286    | 6.65285714      |
| 2007 | 6.5   | 0.7543648  | 63.14285714     | 17.81             | 49.6885714    | 6.57857143      |
| 2008 | 4.9   | 0.75689444 | 60.1            | 28.58             | 47.4285714    | 6.68571429      |
| 2009 | 4.9   | 0.68626001 | 59.71428571     | 26.59             | 47.7857143    | 6.03714286      |
| 2010 | 2.0   | 0.7300792  | 62.74285714     | 26.46             | 50.9971429    | 6.66            |
| 2011 | 6.5   | 0.73079761 | 62.28571429     | 27.03             | 50.9085714    | 6.49428571      |

### III. RESULTS AND DISCUSSION

| Wind Speed(mph)       | 0.04766118   | 0.02611632     | 1.82495789 | 0.11780831 | -0.0162431     | 0.11156551 | -0.0162431  | 0.11156551  |  |

First, a multiple regression analysis was utilized to examine the relationship between temperature, precipitation, dew point, and wind speed and NDVI. The result tells us that all p-values for temperature, precipitation, dew point, and wind speed resulted in p-value value of greater than 0.05. The p-value for the temperature resulted in 0.07 which was close to 0.05. Therefore, this leads us to conclude that these variables do not have significant effect on NDVI variable for the specified months and area of this study. Subsequently, Adjusted R Square value is 0.261, which is not high enough to conclude the independent variables explain the variation of data in dependent variable. The table 2 shows the result of the analysis.

To calculate NDVI, the values were averaged based on the selected months, typically ranging from May to November,

covering the years 2001 to 2011. While significant fluctuations in NDVI between years were not observed, it is important to note that further research on grape vegetation and agricultural practices may be necessary to fully understand any potential effects on the results.

The linear regression model was applied to explore the relationship between NDVI and concord yield. The analysis revealed that the P-value for NDVI was greater than 0.05, indicating that the variable does not contribute significantly to concord yield. Furthermore, the Adjusted R Square value was found to be -0.080, suggesting that the model does not adequately explain the data.

These results were unexpected, as none of the variables were found to be significant. There are several potential explanations for these findings. Firstly, the lack of significant fluctuation in NDVI values may be attributed to the limited geographical scope of the vineyard in Michigan that was selected for the study. Therefore, it's possible that this limited area may not capture sufficient variation in NDVI values. Secondly, the selection of time periods, from bloom date to harvest date, may not be optimal for capturing the significant impact of vegetation index on concord grapes. Further research is needed to identify the specific time of year that has the most significant impact on the vegetation index of concord grapes. Thirdly, the selection of independent variables influencing NDVI could be refined. For instance, the regression results indicated negative coefficients for precipitation and dew points. While this does not necessarily imply a negative impact on NDVI, it suggests that these variables may not positively influence NDVI. Further investigation into the relationships between these variables and NDVI is necessary. Additionally, research on dew point and wind speed is essential to enhance the model's accuracy and comprehensiveness. Finally, conducting preliminary correlation analyses to evaluate the individual relationships with NDVI values would be beneficial. This step would provide insights into the strength and direction of each variable's association with NDVI, aiding in the refinement of the model.

### V. CONCLUSION

Overall, I am grateful for the opportunity to conduct these analyses and learn how to develop the model. While the results were unexpected, they highlight the significant

&gt;

potential for further refinement in the model and underscore the need for continued research on grape vegetation.

#### ACKNOWLEDGMENT

I would like to express my gratitude to Dr. Schulz at University of South Alabama, Prof. Wiesner and Prof. Hendricks at University of Wisconsin-River Falls for their invaluable support and guidance throughout this semester's research.
